Highlights Some insights into the mechanism of the shallow tunnelling method (STM) are given. Nine subway stations in Beijing using different approaches of the STM, combined with site monitoring data, are illustrated. Numerical simulation results are shown to compare various approaches of the STM.

Electrical resistivity (also called specific electrical resistance or volume resistivity) and its converse, electrical conductivity, is a fundamental property of a material that quantifies how strongly it resists or conducts the flow of electric current. A low resistivity indicates a material that readily allows the flow of electric current. Resistivity is commonly represented by the Greek letter

A memristor (*ˈmɛm rɪ stər*); a portmanteau of memory resistor) is a hypothetical non-linear passive two-terminal electrical component relating electric charge and magnetic flux linkage. It was envisioned, and its name coined, in 1971 by circuit theorist Leon Chua. According to the characterizing mathematical relations, the memristor would hypothetically operate in the following way ...

As can be seen in Eq. , in the FE mechanism the specific contact resistance of tunnel Ohmic contacts is strongly dependent both on the Schottky barrier  $\Phi_B$  and on the semiconductor doping  $N_D$  level. In particular, when the thermal energy  $kT$  is much lower compared with the characteristic energy  $E_0$ , the tunnelling of the carriers by FE mechanism is predominant.

Applying DC voltage on the capacitor no conduction current flows through the capacitor if its insulating medium is perfect insulator. This is because there are no free charge carriers in such medium.
